

Villasenor, Hans Rainier A.

While learning about automation in server management, I started to see how all the topics we covered in the course connect in a practical way. During the prelim period, getting introduced to DevOps, Git, and GitHub helped me understand how important teamwork and organized workflows are. Using Ansible also showed me how helpful Infrastructure as Code can be, especially when setting up servers without having to repeat the same steps manually.

As we moved into the midterm topics, I began to understand how automation supports many things happening behind the scenes, like MIS services, workload services, and different types of monitoring. These lessons made me realize how hard it would be to manage all of these by hand, especially when systems grow larger. Automation made more sense to me because it brings consistency, saves time, and reduces simple mistakes.

In the final period, learning about containers and cloud services made everything feel more connected. Containers made me see how applications can be run smoothly across different environments, and cloud services showed how companies manage and scale their systems today. Adding automation on top of these makes everything even more efficient.

Overall, studying automation across these topics helped me understand the bigger picture. It didn't just teach me new tools—it helped me appreciate how modern systems are managed and why automation is such a big deal today. This experience also encouraged me to keep learning more, because every topic felt like a step toward understanding how real-world IT environments actually work.
